What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

イロト イポト イラト イラト

Background What is Agent-based Modeling?

- ABM has been considered as a bottom-up approach modeling behaviors of <u>a group of agents</u>, rather than a representative agent, in a system.
- The representative-agent hypothesis allows for greater ease in solution procedures.
 - It is easier to find the equilibrium (relatively...).
 - This is usually called the **analytical optimization** .

What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

イロト イポト イヨト イヨト

Background What is Agent-based Modeling?

- Examples of the representative-agent models:
 - Profit maximization, utility maximization, or cost/loss minimization...
- Methods of optimization:
 - (1) First-order condition unconstrained optimization
 - (2) Lagrangian multiplier constrained optimization
 - (3) Dynamic optimization
 - (a) Bellman equation (over discrete time), and
 - (b) Hamiltonian multiplier (over continuous time).

Background What is Agent-based Modeling?

• LeBaron and Tesfatsion (2008, 246): "Potentially important real-world factors such as subsistence needs, incomplete markets, imperfect competition, inside money, strategic behavioral interactions, and open-ended learning that tremendously complicate analytical formulations are typically not incorporated"

What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

・ロト ・ 同ト ・ ヨト ・ ヨト

Background What is Agent-based Modeling?

- One important element of ABM is that it allows the possibility of agents' interactions in micro levels with the assumption of bounded-rationality or imperfect information.
- Given agents' heterogenous characteristics and their interactions at the micro level, we can simulate the system and observe changes in the macro level over time according to the system-simulated data.

What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

Background Applications of ABM

- Poli. Sci. (Bendor, Diermeier and Ting, APSR 2003; Fowler, JOP 2006)
 - BDT (2003):
 - A computational model by assuming that voters are adaptively rational voters learn to vote or to stay home in a form of trial-and-error.
 - Voters are reinforced to repeat an action (e.g., vote) in the future given a successful outcome today.
 - The turnout rate is substantially higher than the predictions in rational choice models.
 - Fowler (2006):
 - He revises the BDT model by including habitual voting behavior.
 - Fowler finds his behavioral model is a better fit to the same data BDT use.

What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

Background Genetic Algorithm - The Learning Mechanism

- The genetic algorithm (GA), developed by John Holland (1970), is considered one of the evolutionary algorithms inspired by natural evolution with a core concept of "survival of the fittest".
- The GA describes the evolutionary process of a population of genetic individuals with heterogeneous beliefs in response to the rules of nature.

What is Agent-based Modeling? Genetic Algorithm - The Mechanism of Learning

(日) (同) (三) (三)

This Presentation

We introduce Arifovic (1994) as an example to investigate if the macro-level stability condition (the cobweb theorem) is necessary for a stable cobweb economy under GA.

We would also like to see how to apply the genetic algorithm on a simple economic model.

Important terms:

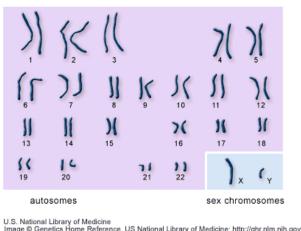

- Genes, Chromosomes, and Populations
 - Chromosomes: Genetic individuals making heterogeneous decisions
 - Genes: Elements of a decision that a genetic individual makes
 - Population: A group of genetic individuals with heterogeneous decisions

Cobweb Model The GA Learning Conclusions

The cobweb model- An Introduction

- It is a classic model which illustrates the dynamic process of prices in **agricultural** markets (Kaldor, 1934).
- Due to a lag between planting and harvesting, farmers cannot adjust the amount of agricultural output immediately to fulfill the demand in the market.
- As a result, farmers make their planting decisions today based on the predicted (or forecasted) price of the agricultural product in the next period.
- If farmers expect <u>the price is high</u> in the next period, they would like to <u>plant more</u> today to make more money tomorrow, and vice versa. (The Law of Supply.)

・ロト ・ 同ト ・ ヨト ・ ヨト

Cobweb Model The GA Learning Conclusions

The cobweb model- An Introduction

- Assuming that farmers "forecast" the price in the next period based on the price they observe today, that is, $P_{t+1}^e = P_t$.
- If the current price level P_t is high (and is higher than the equilibrium price P^* , which is assumed to be unknown for the farmers). It can be written as: $P_{t=1} > P^*$.
 - At time t = 1, farmers would be very happy to plant more today so that they will have more output $(Q_{t=2})$ which can be sold at the high price they expect in the next period.
 - At time t = 2, since all farmers did the same in period 1, there are too much output available, which creates a "surplus" in the market, the price drops sharply at t = 2 due to the excess supply, and it goes below the equilibrium: $P_{t=2} < P^* < P_{t=1}$.

イロト イポト イヨト イヨト

Cobweb Model The GA Learning Conclusions

The cobweb model- An Introduction

- What would be the planting decision for the farmers at *t* = 2?
 - At time t = 2, since they observe the today's price is low, they would expect the price will also be low in the next period (t = 3). Therefore, they decide to plant less today...
 - At time t = 3, since all farmers again are doing the exact same thing, the total output level turns out to be very low this time. $Q_{s,t=3} < Q_{d,t=3}$ (shortage!). Therefore, the price jumps up!

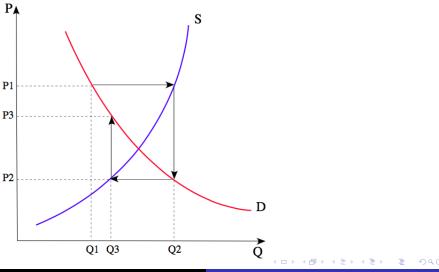

• What would be the planting decision for the farmers at *t* = 3 now?

- At time t = 3, since they observe the today's price is now high again, they would expect the price will also be high in the next period (t = 4). Therefore, they decide to plant more today...
- This story keeps going...

Cobweb Model The GA Learning Conclusions

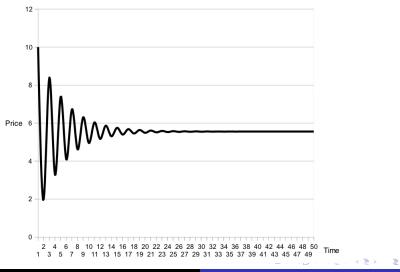

The cobweb model- An Introduction

Cobweb Model The GA Learning Conclusions

The cobweb model - an mathematical illustration

- Arifovic (1994) assumes each firm *i* chooses a production level q_{it} to maximize its expected profit π^e_{it} .
- The cost function for firm *i* is:

$$C_{it} = aq_{it} + \frac{1}{2}bmq_{it}^2$$
, where $a, b > 0$.

• Given the expected price of the good P_t^e at time *t*, firm *i* is maximizing the following profit function:

$$\pi_{it}^{e} = P_{t}^{e} q_{it} - C_{it}(q_{it}) = P_{t}^{e} q_{it} - aq_{it} - \frac{1}{2} bm q_{it}^{2}.$$

• The first order condition for each firm *i* is:

$$P_t^e - a - bmq_{it} = 0 \Rightarrow q_{it} = \frac{P_t^e - a}{bm}$$

Cobweb Model The GA Learning Conclusions

The cobweb model - an mathematical illustration

 Assuming all firms are identical so that q_{it} = q_t ∀i, the aggregate supply in the market is:

$$Q_t = \sum_{i=1}^m q_{it} = mq_t = \frac{P_t^e - a}{b},$$
 (1)

where m = number of firms in the market.

• Assuming that the market demand is a linear function:

$$P_t = \gamma - \theta Q_t, \qquad (2)$$

where $Q_t = \sum q_{it}$.

• In equilibrium where (1)=(2), we can derive the following law of motion for the price level:

$$\frac{\gamma - P_t}{\theta} = \frac{P^e - a}{b} \Rightarrow P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b} P_t^e.$$

Cobweb Model The GA Learning Conclusions

The Cobweb Theorem and Other Expectations Formations

• The dynamics of the price level:

$$P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b} P_t^e.$$

- According to Cobweb Theorem, the model is stable if $\theta/b < 1$, that is, $\theta < b$. However, the model is unstable if $\theta/b > 1$, that is, $\theta > b$.
- Arifovic discusses three types of expectations formations:
 - Static expectations (i.e., $P_t^e = P_{t-1}$):
 - The model is stable only if $\theta/b < 1$.
 - 2 Simple adaptive expectations $(P_t^e = \frac{1}{t} \sum_{s=0}^{t-1} P_s)$:
 - The model is stable in <u>both</u> cases (Carlson, 1968).
 - **3** Least squares learning $(P_t^e = \beta_t P_{t-1}, \beta_t = \text{OLS coefficient})$:
 - The model is stable only if $\theta/b < 1$ (Bray and Savin, 1986).

Cobweb Model The GA Learning Conclusions

The Basic GA and Arifovic's New GA Operator

- Arifovic (1994) simulates the cobweb model based on three basic genetic operators in the GA simulations:
 - (1) reproduction, (2) mutation, and (3) crossover.
- She also introduces a new operator, called *election*, in the simulations.
- Election is an operator to "examine" the fitness of newly generated (or offspring) chromosomes and then compare them with their parent chromosomes.

イロト イポト イラト イラト

Cobweb Model The GA Learning Conclusions

New GA Operator - Arifovic (1991, 1994)

- The Rules of Election:
 - Both offspring chromosomes <u>are elected</u> to be in the new population at time t+1 if $E_t\left(V\left(C_{it+1}^{offspring}\right)\right) > V\left(C_{it}^{Parent}\right)$.
 - However, if only one new chromosome has a higher fitness value than their parents, the one with lower value will not enter the new population, but one of the parents with a higher values stays in the new population.
 - If both new chromosomes have lower values than their parents $E_t\left(V\left(C_{it+1}^{offspring}\right)\right) < V\left(C_{it}^{Parent}\right)$, they cannot enter but their parents stay in the new population.

Cobweb Model The GA Learning Conclusions

Conclusions

- Arifovic (1994) introduces the GA procedure as an alternative learning mechanism.
- This alternative learning mechanism mimics social behavior:
 - imitation, communication, experiment, and examination.
- Arifovic uses the GA simulated data to compare with the data generated in human-subject experiments (Wellford, 1989).
 - In an unstable case of the cobweb model, the divergent patterns *do not* happen under both GA learning and human-subject experiments.
 - Price and quantity fluctuate around the equilibrium in *basic* GA learning and human-subject experiments.

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

イロト イポト イヨト イヨト

Notations under the GA

- Chromosome C_i consists of a set of 0 and 1, where L is the length of a chromosome (the number of genes).
- $B^{max}(C_i) = 2^L 1$ represents the maximum numerical value of a chromosome with the length *L*.
 - For example, if L = 10, the maximum value of a chromosome:

$$\mathsf{B}(1111111111) = 2^{10} - 1 = 1023.$$

• We can use the *B* operator to compute a numerical value of a chromosome (e.g., *C_i* = 0100101110) :

$$B(0100101110) = 0 \times 2^9 + 1 \times 2^8 + 0 \times 2^7 + 0 \times 2^6 + 1 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + 1 \times 2^1 + 0 \times 2^0 = 302.$$

A Simple Profit Maximization Problem **The GA Operators** MATLAB codes Simulations

(日) (同) (三) (三)

Notations under the GA

- Assume that there are M = 8 genetic individuals. For L = 10, we can generate an initial genetic population P₀ in an M × L matrix (that is, 8 × 10 matrix):
- For example:

$$P_0 = \begin{array}{c} 0100101110\\ 111010100\\ 0101110100\\ 0100001010\\ 11101000\\ 0101101101\\ 110010100\\ 0100011100 \end{array}$$

A Simple Profit Maximization Problem **The GA Operators** MATLAB codes Simulations

イロト イポト イヨト イヨト

Notations under the GA

- According to the problem of profit maximization, if a = 200, b = 4, and e = 40, then $q^* = 20$.
- In this case, the maximum value of a chromosome can be too large for this problem $(B^{max} = 1023)$.
- We can define a maximum economic value for a chromosomes $V(C_i)$ based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i),$$

where $V(C_i) \in [0, U^{max}]$ for $B(C_i) \in [0, B^{max}]$, and U^{max} is the maximum economic value in the problem.

A Simple Profit Maximization Problem **The GA Operators** MATLAB codes Simulations

(日) (同) (三) (三)

Notations under the GA

• An economic value for a chromosomes $V(C_i)$ based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i).$$

• For example, given the maximum output level is $U^{max} = 100$, and $C_i = 0100101110$ (i.e., $B(C_i) = 302$), we can calculate the output level for firm *i*:

$$q_i = V(C_i) = \frac{100}{1023} \times 302 = 29.52 \approx 30.$$

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

Notations under the GA

- Is firm *i* doing a good job? We need to evaluate firm *i* using a fitness function $F(C_i)$.
- The profit function is used as the fitness function in this case:

$$F(C_i) = \pi(V(C_i))$$

= $\pi(q_i) = (a - bq_i)q_i - (d + eq_i).$

In this case,

$$F(C_i) = \pi(V(C_i))$$

= $\pi(29.52) = (200 - 4(29.52))(29.52) - (50 + 40(29.52))$
= 1187.48.

• The maximum profit is (for q = 20):

$$F^{max} = \pi(q^*) = \pi(20) = 1550.$$

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

The GA Operators Reproduction \Rightarrow Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
 - Higher fitness value \Rightarrow higher probability of being drawn to the new population.
- The relative fitness function is:

$$R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^{M} F(C_{m,t})},$$

where $\sum_{i \in M} R(C_{i,t}) = 1$.

 The relative fitness value R(C_{i,t}) gives us the probability chromosome i is copied to the new population at time t + 1.

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

イロト イポト イヨト イヨト

- What if $F(C_{i,t})$ is negative for some firm *i*? (a negative profit?)
- Goldberg (1989) proposes a scaled relative fitness function:

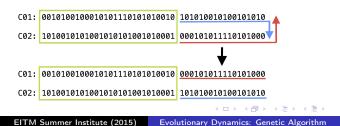

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} F(C_{m,t}) + MA},$$

where A is a constant such that $A > -\min_{C_i \in P_t} F(C_{i,t})$.

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

The GA Operators Crossover

- A crossover point will be randomly chosen to separate each chromosome into two sub-strings.
- Two "offspring" chromosomes will be formed by swapping the right-sided parents' substrings with probability κ .

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

イロト イポト イヨト イヨト

The GA Operators Crossover

3

Converting Binary Value into Numerical Value

```
%Calculate the real value of each chromosome: "BC"
87
88 -
       m2 = 2 * ones(n,1);
      □ for i=1:n
89 -
90 -
            m2(i,1)=m2(i,1).^{(n-i)};
91 -
       end
92
93 -
       BC = ones(m, 1);
94 -
      □ for i=1:m
95 -
            BC(i,1)=gen(i,:) * m2; %Converting Binary # to Decimal # for each i
96 -
       end
97
```

• For example,

$$B(0100101110) = 0 \times 2^9 + 1 \times 2^8 + 0 \times 2^7 + 0 \times 2^6 + 1 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + 1 \times 2^1 + 0 \times 2^0 = 302.$$

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

(日) (同) (三) (三)

Notations under the GA

• An economic value for a chromosomes $V(C_i)$ based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i).$$

• For example, given the maximum output level is $U^{max} = 100$, and $C_i = 0100101110$ (i.e., $B(C_i) = 302$), we can calculate the output level for firm *i*:

$$q_i = V(C_i) = \frac{100}{1023} \times 302 = 29.52 \approx 30.$$

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

Notations under the GA

- Is firm *i* doing a good job? We need to evaluate firm *i* using a fitness function $F(C_i)$.
- The profit function is used as the fitness function in this case:

$$F(C_i) = \pi(V(C_i))$$

= $\pi(q_i) = (a - bq_i)q_i - (d + eq_i).$

In this case,

$$F(C_i) = \pi(V(C_i))$$

= $\pi(29.52) = (200 - 4(29.52))(29.52) - (50 + 40(29.52))$
= 1187.48.

• The maximum profit is (for q = 20):

$$F^{max} = \pi(q^*) = \pi(20) = 1550.$$

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

The GA Operators Reproduction \Rightarrow Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
 - Higher fitness value \Rightarrow higher probability of being drawn to the new population.
- The relative fitness function is:

$$R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^{M} F(C_{m,t})},$$

where $\sum_{i \in M} R(C_{i,t}) = 1$.

 The relative fitness value R(C_{i,t}) gives us the probability chromosome i is copied to the new population at time t + 1.

A Simple Profit Maximization Problem The GA Operators MATLAB Codes Simulations

(日) (同) (三) (三)

The GA Operators Reproduction

122	%This is the code for Reproduction
123 -	norm_fit 🗮 SC
124 -	<pre>selected = rand(size(SC))</pre>
125 -	<pre>sum_fit = 0;</pre>
126 -	<pre>of for i=1:length(SC)</pre>
127 -	<pre>sum_fit = sum_fit + norm_fit(i)</pre>
128 -	
129 -	<pre>selected(index) = i*ones(size(index))</pre>
130 -	end
131 -	gen 🗮 gen(selected,:)
132	

Goldberg (1989) proposes a scaled relative fitness function:

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} F(C_{m,t}) + MA},$$

where A is a constant such that $A > -\min_{C_i \in P_t} F(C_{i,t})$.

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

The Basic GA Simulations

- Market Parameters:
 - Demand: a = 200, and b = 400.
 - Supply: d = 50, and e = 40.
 - Optimal output: $q^* = 20$.
- GA Parameters:
 - *M* = 200 (200 genetic agents)
 - L = 16, therefore $B^{max} = 65535$.
 - $U^{max} = 50$ (maximum output $q^{max} = 50$)
 - $\kappa = 0.3$ (probability of crossover)
 - $\mu = 0.0033$ (probability of mutation)
 - *t* = 500 (500 generations)

The Augmented GA Simulations The Standard Deviation of Output Level over time

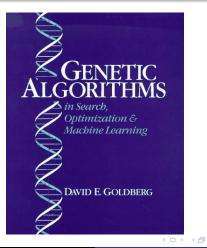

Concluding Remarks

- Why do we use the GA (or ABM in general) for political science / economics research??
 - Some models are mathematically intractable (we cannot find a closed-form equilibrium).
 - No strong assumptions imposed (such as, efficient markets, rational agents, representative agent hypothesis).
 - It allows non-linearity in a theoretical model.
 - It is relatively easier to capture equilibrium (equilibria) in a multi-national, multi-sector model.
